NEW QUESTION: 1

Which protocol provides port-based access control and authentication?

- A. 802.1P
- B. 802.1Q
- C. 802.1W
- D. 802.1X

Answer: D

Explanation:

Explanation/Reference:

Explanation:

IEEE 802.1X provides port-based access control and authentication.

IEEE 802.1X is a client-server based access control model. If IEEE 802.1X is enabled on a switch interface, the interface is in an unauthorized state until it is authenticated. Until the station is authenticated, the only protocols allowed through switch ports are:

CDP

STP

EAP-over-LAN (EAPOL is the only type of traffic accepted from a station) The supplicant PAE sends EAPOL packets that indicate its request for access through the switch to the LAN. The switch performs the authenticator role by processing the EAPOL packets from the port-attached supplicant PAE and forwarding an authentication request to the authentication server. The only supported authentication server is a Remote Access Dial-In User Server (RADIUS) server with EAP extensions. The authentication server checks the identity of the client (the supplicant PAE) and will either accept or reject the request. If the server accepts the request, the port is authorized and the switch will send and receive all frames. If it fails, only EAPOL packets will continue to be processed. Once the client is finished with the connection, an EAPOL logoff is issued, and the switch port once again becomes unauthorized.

Below is a sample configuration to enable 802.1X authentication and enable it on an interface:

```
switch(config)# aaa new-model
```

```
switch(config)# aaa authentication dot1x default group radius
```

```
switch(config)# dot1x system-auth-control
```

```
switch(config-if)# dot1x port-control auto
```

802.1w is the standard for Rapid Spanning Tree Protocol (RSTP). It is not related to port-based access control and authentication.

802.1P is a method for assigning priority to packets traversing a network. It is not related to port-based access control and authentication.

802.1Q describes VLAN tagging. It is not related to port-based access control and authentication.

About CRLs Certificate Revocation Lists provide the security appliance with one means of determining whether a certificate that is within its valid time range has been revoked by its

issuing CA. CRL configuration is a part of the configuration of a trustpoint. You can configure the security appliance to make CRL checks mandatory when authenticating a certificate (revocation-check crl command). You can also make the CRL check optional by adding the none argument (revocation-check crl none command), which allows the certificate authentication to succeed when the CA is unavailable to provide updated CRL data. The security appliance can retrieve CRLs from CAs using HTTP, SCEP, or LDAP. CRLs retrieved for each trustpoint are cached for a length of time configurable for each trustpoint. When the security appliance has cached a CRL for more than the length of time it is configured to cache CRLs, the security appliance considers the CRL too old to be reliable, or "stale". The security appliance attempts to retrieve a newer version of the CRL the next time a certificate authentication requires checking the stale CRL.
